Reciprocating internal combustion engines — Exhaust emission measurement

Part 9: Test cycles and test procedures for measurement of exhaust gas
smoke emissions from compression ignition engines using an opacimeter

National foreword

This British Standard is the UK implementation of ISO 8178-9:2019. It supersedes BS ISO 8178-10:2002 and BS ISO 8178-9:2012, which are withdrawn.

The UK participation in its preparation was entrusted to Technical Committee MCE/14/-/3, RIC Engines - Performance and emissions.

A list of organizations represented on this committee can be obtained on request to its secretary.

This publication does not purport to include all the necessary provisions of a contract. Users are responsible for its correct application.

Foreword

ISO (the International Organization for Standardization) is a worldwide federation of national standards bodies (ISO member bodies). The work of preparing International Standards is normally carried out through ISO technical committees. Each member body interested in a subject for which a technical committee has been established has the right to be represented on that committee. International organizations, governmental and non-governmental, in liaison with ISO, also take part in the work. ISO collaborates closely with the International Electrotechnical Commission (IEC) on all matters of electrotechnical standardization.

The procedures used to develop this document and those intended for its further maintenance are described in the ISO/IEC Directives, Part 1. In particular the different approval criteria needed for the different types of ISO documents should be noted. This document was drafted in accordance with the editorial rules of the ISO/IEC Directives, Part 2 (see www.iso.org/directives).

Attention is drawn to the possibility that some of the elements of this document may be the subject of patent rights. ISO shall not be held responsible for identifying any or all such patent rights. Details of any patent rights identified during the development of the document will be in the Introduction and/or on the ISO list of patent declarations received (see www.iso.org/patents).

Any trade name used in this document is information given for the convenience of users and does not constitute an endorsement.

For an explanation of the voluntary nature of standards, the meaning of ISO specific terms and expressions related to conformity assessment, as well as information about ISO's adherence to the World Trade Organization (WTO) principles in the Technical Barriers to Trade (TBT), see www.iso.org/iso/foreword.html.

This document was prepared by Technical Committee ISO/TC 70, *Internal combustion engines*, Subcommittee SC 8, *Exhaust gas emission measurement*.

This third edition cancels and replaces ISO 8178-9:2012 and ISO 8178-10:2002, which have been technically revised.

The main changes compared to the previous editions are as follows:

- ISO 8178-10:2002 has been incorporated in this document;
- terms and definitions have been harmonized within the ISO 8178 series and differences to other ISO standards have been described where applicable;
- redundant specifications of testing equipment, calibration and verification requirements have been deleted or replaced by references to other parts of the ISO 8178 series;
- ambient density smoke correction has been deleted;
- order of annexes has been changed;
- [Annex A](#) has been added - Overview particulate and soot measurement methods;
- [Annex H](#) has been added - Test at steady speeds over full-load curve;
- [Annex I](#) has been added - Reporting smoke tests results.

A list of all parts in the ISO 8178 series can be found on the ISO website.

Any feedback or questions on this document should be directed to the user's national standards body. A complete listing of these bodies can be found at www.iso.org/members.html.

Introduction

On a global scale, there are currently many smoke measurement procedures in various forms. Some of these smoke measurement procedures are designed for test bed testing and intended to be used for certification or type-approval purposes. Others are designed for field-testing and can be used in inspection and maintenance programs. Different smoke measurement methods exist to meet the needs of various regulatory agencies and industries.

The two smoke measurement methods typically used are (1) the FSN method, measuring light absorption based on the change in optical reflectance of visible light from a blackening filter paper relative to the clean filter (filter-type smoke meters) and (2) the exhaust gas opacity method, measuring transmittance based on light extinction caused by absorption and scattering of light (opacimeter-type smoke meters).

[Figure A.1](#) in [Annex A](#) shows an overview of the measurement methods specified by an ISO standard including FSN and opacity respectively.

ISO 8178-4 specifies a number of different test cycles to be used to characterize and control gaseous and particulate emissions from nonroad engines using a variety of steady-state and transient operating conditions. The test cycles in ISO 8178-4 were developed in recognition of the differing operating characteristics of various categories of nonroad machines. Likewise, different smoke test cycles can be appropriate for different categories of nonroad engines and machines.

Reciprocating internal combustion engines — Exhaust emission measurement —

Part 9:

Test cycles and test procedures for measurement of exhaust gas smoke emissions from compression ignition engines using an opacimeter

1 Scope

This document specifies the measurement procedures and test cycles for the evaluation of smoke emissions from compression ignition engines using an opacimeter. The tests are carried out under steady-state and transient operation using tests cycles which are representative of a given application.

The smoke testing is conducted using opacimeter-type smoke meters which operate on the light extinction principle. The purpose of this document is to define the smoke test cycles and the methods used to measure the opacity and for the determination of the light absorption coefficient. It allows the use of either full-flow or partial-flow opacimeters and corrects for differences in rise time between the two types of opacimeters. Specifications of the apparatus for the measurement of opacity can be found in ISO 11614. The test procedures and measurement techniques described in this document are applicable to reciprocating internal combustion (RIC) engines in general. [Annex D](#), [Annex E](#), [Annex F](#) and [Annex G](#) each contains a test cycle that is relevant only for those specific applications listed in the first subclause of that annex. Where possible, the smoke test cycle described in the annex utilizes the engine and machine categories developed in ISO 8178-4.

For certain categories of non-road engines “at site” rather than “test bed” smoke test procedures can prove to be necessary. For engines used in machinery covered by additional requirements (e.g. occupational health and safety regulations), additional test conditions and special evaluation methods can apply.

2 Normative references

The following documents are referred to in the text in such a way that some or all of their content constitutes requirements of this document. For dated references, only the edition cited applies. For undated references, the latest edition of the referenced document (including any amendments) applies.
